#### General Framework for Linear Classifiers

- $X \subseteq \mathbb{R}^n$  is the input space and Y is the output domain;
- - $Y = \{1, 2, \dots, m\}$  for *m*-class classification;
  - $Y \subseteq \mathbb{R}$  for regression;
- A training sequence is a sequence

$$S = \left( \begin{pmatrix} \mathbf{x}_1 \\ y_1 \end{pmatrix}, \dots, \begin{pmatrix} \mathbf{x}_\ell \\ y_\ell \end{pmatrix} 
ight),$$

where  $\mathbf{x}_i \in X$  are examples or instances, and  $y_i \in Y$  are the labels.

#### Points and Hyperplanes

Let  $\mathbf{w}'\mathbf{x} + b = 0$  be a hyperplane H in  $\mathbb{R}^n$ . The vector  $\mathbf{w}$  is orthogonal to H, so the line that passes through  $\mathbf{x}_0$  and is orthogonal to the hyperplane is

 $\mathbf{x} - \mathbf{x}_0 = a\mathbf{w}$ .

The intersection of this line with the hyperplane is  $\mathbf{w}'(\mathbf{x}_0 + a\mathbf{w}) + b = 0$ , so

$$\mathsf{a} = -rac{\mathsf{w}' \mathsf{x}_0 + b}{\parallel \mathsf{w} \parallel^2}.$$

ヘロト 人間ト 人間ト 人間ト

### Points and Hyperplanes

The projection of  $\mathbf{x}_0$  on the hyperplane H given by  $\mathbf{w}'\mathbf{x} + b = 0$  is

$$\mathbf{z} = \mathbf{x}_0 - \frac{\mathbf{w}'\mathbf{x}_0 + b}{\parallel \mathbf{w} \parallel^2} \mathbf{w}$$

and the distance from  $\mathbf{x}_0$  to H is  $\frac{|\mathbf{w}'\mathbf{x}_0+b|}{||\mathbf{w}||}$ . When  $||\mathbf{w}|| = 1$  this distance is  $|\mathbf{w}'\mathbf{x}_0 + b|$ . The two half-spaces determined by H are characterized by  $\mathbf{w}'\mathbf{x} + b > 0$  and by  $\mathbf{w}'\mathbf{x} + b < 0$ .

Prof. Dan A. Simovici (UMB)

## Learning using Perceptrons

Perceptrons were introduced in [4] as models of learning in the brain. A training sequence

$$S = \left( \begin{pmatrix} \mathsf{x}_1 \\ y_1 \end{pmatrix}, \dots, \begin{pmatrix} \mathsf{x}_\ell \\ y_\ell \end{pmatrix} 
ight)$$

is linearly separable if there exists a hyperplane  $\mathbf{w'x} + b = 0$  such that  $\mathbf{w'x}_i + b \ge 0$  if  $y_i = 1$  and  $\mathbf{w'x}_i + b < 0$  if  $y_i = -1$ .

イロト 不得 トイヨト イヨト

#### Linearly Separable vs. Unseparable Data

Task of Learning algorithm (perceptron): find a hyperplane for a linearly separable data set.

### Features of the Learning Algorithm

- a hyperplane H defined by  $f(\mathbf{x}) = \mathbf{w}'\mathbf{x} + b = 0$ ;
- w is the weight vector and b is the bias;
- if f(x) ≥ 0, x is a positive example; otherwise, it is a negative example;
- the radius of a ball centered in **0** that includes all examples is  $R = \max\{\|\mathbf{x}_i\| \mid 1 \leq i \leq \ell\};$
- the functional margin of  $\begin{pmatrix} \mathbf{x}_i \\ y_i \end{pmatrix}$  relative to the hyperplane  $\mathbf{w}'\mathbf{x} + b = 0$ is  $\gamma_i = y_i(\mathbf{w}'\mathbf{x}_i + b)$ ;  $\gamma = min\gamma_i$  is the margin of the hyperplane Hrelative to S;
- if  $y_i$  and  $\mathbf{w}'\mathbf{x}_i + b$  have the same sign, then  $\begin{pmatrix} \mathbf{x}_i \\ y_i \end{pmatrix}$  is classified correctly  $(\gamma_i > 0)$ ; otherwise, is incorrectly classified  $(\gamma_i \leq 0)$ .

### Rosenblatt-Novikoff Theorem

(variant of Cristianini and Shawe-Taylor [1] of Novikoff's Proof [3])

#### Theorem

Let  $S = \left( \begin{pmatrix} \mathbf{x}_1 \\ y_1 \end{pmatrix}, \dots, \begin{pmatrix} \mathbf{x}_\ell \\ y_\ell \end{pmatrix} \right)$  be a non-trivial training sequence that is linearly separable, and let  $R = \max\{ \| \mathbf{x}_i \| \mid 1 \leq i \leq \ell \}$ . Suppose there exists an optimal weight vector  $\mathbf{w}_{opt}$  and an optimal bias  $b_{opt}$  such that

$$\parallel \mathbf{w}_{opt} \parallel = 1 \text{ and } y_i(\mathbf{w}_{opt}'\mathbf{x}_i + b_{opt}) \geqslant \gamma,$$

for  $1 \leq i \leq \ell$ . The, the number of mistakes made by the algorithm is at most

$$\left(\frac{2R}{\gamma}\right)^{2}$$

## Proof

Let

• t be the update counter;

and let

$$\hat{\mathbf{w}} = egin{pmatrix} \mathbf{w} \ rac{b}{R} \end{pmatrix}$$
 and  $\hat{\mathbf{x}}_i = egin{pmatrix} \mathbf{x}_i \ R \end{pmatrix}$ 

for  $1 \leq i \leq \ell$ .

The algorithm begins with an augmented vector  $\hat{\bm{w}}_0 = \bm{0}$  and updates it at each mistake.

Let  $\hat{w}_{t-1}$  be the augmented weight vector prior to the  $t^{\rm th}$  mistake. The  $t^{\rm th}$  update is performed when

$$y_i \hat{\mathbf{w}}_{t-1}' \hat{\mathbf{x}}_i = y_i (\mathbf{w}_{t-1}' \mathbf{x}_i + b_{t-1}) \leqslant 0,$$

where  $(\mathbf{x}_i, y_i)$  is the example incorrectly classified by

$$\hat{\mathbf{w}}_{t-1} = \begin{pmatrix} \mathbf{w}_{t-1} \\ \frac{b_{t-1}}{R} \end{pmatrix}.$$

< 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

The update is

$$\hat{\mathbf{w}}_{t} = \begin{pmatrix} \mathbf{w}_{t} \\ \frac{b_{t}}{R} \end{pmatrix} = \begin{pmatrix} \mathbf{w}_{t-1} + \eta y_{i} \mathbf{x}_{i} \\ \frac{b_{t-1} + \eta y_{i} \mathbf{x}_{i}}{R} \end{pmatrix}$$

$$= \begin{pmatrix} \mathbf{w}_{t-1} + \eta y_{i} \mathbf{x}_{i} \\ \frac{b_{t-1}}{R} + \eta y_{i} R \end{pmatrix} = \begin{pmatrix} \mathbf{w}_{t-1} \\ \frac{b_{t-1}}{R} \end{pmatrix} + \begin{pmatrix} \eta y_{i} \mathbf{x}_{i} \\ \eta y_{i} R \end{pmatrix}$$

$$= \hat{\mathbf{w}}_{t-1} + \eta y_{i} \hat{\mathbf{x}}_{i},$$

where we used the fact that  $b_t = b_{t-1} + \eta y_i R^2$ . By hypothesis, we have

$$y_i \hat{\mathbf{w}}'_{opt} \hat{\mathbf{x}}_i = y_i \left( \mathbf{w}'_{opt} \ \frac{b}{R} \right) \begin{pmatrix} \mathbf{x}_i \\ R \end{pmatrix} = y_i (\mathbf{w}'_{opt} \mathbf{x}_i + b) \ge \gamma,$$

which implies

$$\hat{\mathbf{w}}_{opt}'\hat{\mathbf{w}}_t = \hat{\mathbf{w}}_{opt}'\hat{\mathbf{w}}_{t-1}' + \eta y_i \hat{\mathbf{w}}_{opt}'\hat{\mathbf{x}}_i \geqslant \hat{\mathbf{w}}_{opt}'\hat{\mathbf{w}}_{t-1} + \eta \gamma.$$

3

(4月) (4日) (4日)

By repeated application of the inequality  $\hat{\mathbf{w}}'_{opt}\hat{\mathbf{w}}_t \ge \eta \gamma$  we obtain

 $\hat{\mathbf{w}}_{opt}'\mathbf{w}_t \ge t\eta\gamma.$ 

Since  $\hat{\mathbf{w}}_t = \hat{\mathbf{w}}_{t-1} + \eta y_i \hat{\mathbf{x}}_i$ , we have

$$\begin{aligned} \| \, \hat{\mathbf{w}}_t \, \|^2 &= \, \hat{\mathbf{w}}_t' \hat{\mathbf{w}}_t = (\hat{\mathbf{w}}_{t-1}' + \eta y_i \hat{\mathbf{x}}_i') (\hat{\mathbf{w}}_{t-1} + \eta y_i \hat{\mathbf{x}}_i) \\ &= \, \| \, \hat{\mathbf{w}}_{t-1} \, \|^2 + 2\eta y_i \hat{\mathbf{w}}_{t-1}' \hat{\mathbf{x}}_i + \eta^2 \, \| \, \hat{\mathbf{x}}_i \, \|^2 \\ &\quad \text{(because } y_i \hat{\mathbf{w}}_{t-1}' \hat{\mathbf{x}}_i \leqslant 0 \text{ when an update occurs)} \\ &\leqslant \, \| \, \hat{\mathbf{w}}_{t-1} \, \|^2 + \eta^2 \, \| \, \hat{\mathbf{x}}_i \, \|^2 \\ &\leqslant \, \| \, \hat{\mathbf{w}}_{t-1} \, \|^2 + \eta^2 (\| \, \mathbf{x}_i \, \|^2 + R^2) \\ &\leqslant \, \| \, \hat{\mathbf{w}}_{t-1} \, \|^2 + 2\eta^2 R^2, \end{aligned}$$

which implies  $\| \hat{\mathbf{w}}_t \|^2 \leq 2t\eta^2 R^2$ .

イロト 不得下 イヨト イヨト 二日

By combining the inequalities

$$\hat{\mathbf{w}}'_{opt}\mathbf{w}_t \geqslant t\eta\gamma$$
 and  $\parallel \hat{\mathbf{w}}_t \parallel^2 \leqslant 2t\eta^2 R^2$ 

we have

$$\| \hat{\mathbf{w}}_{opt} \| \sqrt{2t} \eta R \ge \| \hat{\mathbf{w}}_{opt} \| \| \hat{\mathbf{w}}_t \| \ge \hat{\mathbf{w}}_{opt}' \hat{\mathbf{w}}_t \ge t \eta \gamma,$$

which implies

$$t \leqslant 2 \left(rac{R}{\gamma}
ight)^2 \parallel \hat{\mathbf{w}}_{opt} \parallel^2 \leqslant \left(rac{2R}{\gamma}
ight)^2$$

because  $b_{opt} \leq R$  for a non-trivial separation of data and hence

$$\parallel \hat{\mathbf{w}}_{opt} \parallel^2 \leq \parallel \mathbf{w}_{opt} \parallel^2 +1 = 2.$$

3

ヘロト 人間 ト 人 ヨ ト 一

#### Definition

Let  $\gamma > 0$ . The margin slack variable of an example  $(\mathbf{x}_i, y_i)$  with respect to a hyperplane H given by  $\mathbf{w}'\mathbf{x} + b = 0$  and the target margin  $\gamma$  is

$$\xi((\mathbf{x}_i, y), H, \gamma) = \xi_i = \max\{0, \gamma - y_i(\mathbf{w}'\mathbf{x}_i + b)\}$$

- ξ<sub>i</sub> measures how much a point fails to have a margin of γ from H; in any case, ξ<sub>i</sub> ≥ γ − y<sub>i</sub>(w'x<sub>i</sub> + b), or y<sub>i</sub>(w'x<sub>i</sub> + b) + ξ<sub>i</sub> ≥ γ;
- if  $\xi_i > \gamma$ , then  $\mathbf{x}_i$  is missclassified by H;
- the norm || ξ || measures the amount by which the training sequence fails to have margin γ;
- points that are correctly classfied have their margin slack variable equal to 0.

・ロト ・四ト ・ヨト ・

The size of the margin slack variables for two missclassified examples for a hyperplane.

Remaining points have their slack variable equal to 0 since they have a margin larger than  $\gamma.$ 

## Freund-Shapire Theorem

#### Theorem

Let S be a non-trivial training sequence with no duplicate examples which is included in the ball  $B(\mathbf{0}, R)$ . If H is a hyperplane  $\mathbf{w}'\mathbf{x} + b = 0$  with  $\|\mathbf{w}\| = 1$  and  $\gamma > 0$ , let

$$D = \parallel \xi \parallel = \sqrt{\sum_{i=1}^{n} \xi_i^2}.$$

The number of mistakes in the first execution of the for loop of the perceptron algorithm is bounded by

$$\left(\frac{2(R+D)}{\gamma}\right)^2$$

(4 間) トイヨト イヨト

### Proof

Define a set of extended examples  $\tilde{X}$  and an extended weight vector:

$$\tilde{\mathbf{x}}_{i} = \begin{pmatrix} \mathbf{x}_{i} \\ \mathbf{e}_{i}\Delta \end{pmatrix} = \begin{pmatrix} \mathbf{x}_{i} \\ 0 \\ \vdots \\ \Delta \\ \vdots \\ 0 \end{pmatrix} \text{ and } \tilde{\mathbf{w}} = \begin{pmatrix} \mathbf{w} \\ \frac{y_{1}\xi_{1}}{\Delta} \\ \vdots \\ \frac{y_{m}\xi_{m}}{\Delta} \end{pmatrix},$$

where  $\Delta$  is a parameter. Note that for  $\tilde{R} = \max\{\| \mathbf{x}_i \| | 1 \leq i \leq m\}$  we have  $\tilde{R}^2 = R^2 + \Delta^2$ . Also,  $\mathbf{\tilde{w}}'\mathbf{\tilde{x}}_i = \mathbf{w}'\mathbf{x}_i + y_i\xi_i$  and therefore,

$$y_i(\tilde{\mathbf{w}}'\tilde{\mathbf{x}}_i + b) = y_i(\mathbf{w}'\mathbf{x}_i + y_i\xi_i + b)$$
  
=  $y_i(\mathbf{w}'\mathbf{x}_i + b) + y_i^2\xi_i = y_i(\mathbf{w}'\mathbf{x}_i + b) + \xi_i \ge \gamma.$ 

• the inequality  $y_i(\tilde{\mathbf{w}}'\tilde{\mathbf{x}}_i + b) \ge \gamma$  can be written as

$$y_i(rac{1}{\parallel ilde{\mathbf{w}} \parallel} ilde{\mathbf{w}}' ilde{\mathbf{x}}_i + rac{1}{\parallel ilde{\mathbf{w}} \parallel} b) \geqslant rac{\gamma}{\parallel ilde{\mathbf{w}} \parallel};$$

• 
$$\| \tilde{\mathbf{w}} \| = \sqrt{\sum_{i=1}^{n} w_i^2 + \frac{D^2}{\Delta^2}} = \sqrt{1 + \frac{D^2}{\Delta^2}};$$

Rosenblatt's theorem can be applied if the norm of the optimal weight vector is 1 and this is case for || w w; therefore, we need to replace the margin by

$$ilde{\gamma} = rac{\gamma}{\parallel ilde{\mathbf{w}} \parallel} = rac{\gamma}{\sqrt{1 + rac{D^2}{\Delta^2}}}.$$

イロト イポト イヨト イヨト

Since he training examples have non-zero entries in different coordinates, running the perceptron algorithm for the first **for** loop on  $\tilde{X}$  has the same effect as running it on X, so the number of mistakes is bounded by

$$egin{aligned} &\left(rac{2 ilde{R}}{ ilde{\gamma}}
ight)^2 &= rac{4(R^2+\Delta^2)(1+rac{D^2}{\Delta^2})}{\gamma^2} \ &= rac{4}{\gamma}\left(R^2+D^2+\Delta^2+rac{R^2D^2}{\Delta^2}
ight). \end{aligned}$$

The optimal value is obtained when  $\Delta = \sqrt{RD}$ , which equals

$$\left(\frac{2(R+D)}{\gamma}\right)^2$$

ヘロト 人間ト 人間ト 人目ト

### Remark

- since *D* can be defined for every hyperplane, the Freund-Shapire bound does not assume that the data is linearly separable;
- the perceptron algorithm works by adding missclassified positive examples and by subtracting missclassified negative examples to an initially arbitrary weight vector;
- if the initial weight vector is  ${\bf 0}$  the final weight vector is a linear combination of the examples

$$\mathbf{w} = \sum_{i=1}^{\ell} a_i y_i \mathbf{x}_i;$$

*a<sub>i</sub>* are positive values proportional to the number of times missclassifiation of *x<sub>i</sub>* triggered updates; *a<sub>i</sub>* is the embedding strength of *x<sub>i</sub>*.

< ロ > < 同 > < 回 > < 回 > < 回 > <

The decision function is

$$h(\mathbf{x}) = sign(\mathbf{w}'\mathbf{x} + b)$$
  
= sign  $\left( \left( \sum_{i=1}^{\ell} a_i y_i \mathbf{x}_i \right)' \mathbf{x} + b \right)$   
= sign  $\left( \sum_{i=1}^{\ell} a_i y_i (\mathbf{x}'_i \mathbf{x}) + b \right)$ 

which allows the expression of the perceptron algorithm in the dual form. Note that the learning rate does not appear in the dual form.

## The Dual Perceptron Algorithm

Algorithm 1.2: Dual Learning Algorithm for Perceptron **Data**: labelled training sequence S **Result**: vector **a** and parameter b 1 initialize  $\mathbf{a} = \mathbf{0}$ . b = 0: 2  $R = \max\{ \| \mathbf{x}_i \| \mid 1 \leq i \leq \ell \};$ 3 repeat for i = 1 to  $\ell$  do 4 if  $y_i\left(\sum_{j=1}^{\ell}a_jy_j\mathbf{x}_j\mathbf{x}_i+b\right)\leqslant 0$  then 5 6  $a_i = a_i + 1;$  $b = b + v_i R^2$ ; 7 8 end end 9 0 until no mistakes are made in the for loop ; return **a**, b to define h; 1

- the fact that points that are harder to learn have larger α<sub>i</sub>s can be used to rank the data according to their information content;
- since the number of updates equals the number of mistakes and each update causes 1 to be added to exactly one of its components, the 1-norm of α satisfies the inequality

$$\| \alpha \|_{1} \leqslant \left(\frac{2R}{\gamma}\right)^{2};$$

this norm can be viewed as a measure of complexity of the target concept;

 the training data enter the algorithm through the matrix G = (x'<sub>i</sub>x<sub>j</sub>), known as the Gram matrix.
