Therac-25 Radiation Overdosing (1985-87)

- Radiation machine for treatment of cancer patients
- At least 6 cases of overdose in period 1985–1987 (≈ 100-times dose)
- Three cancer patients died
- Source: Design error in the control software (race condition)
January 1990: problem in New York City leads to 9 hour-outage of large parts of U.S. telephone network

- Cost: several $100 million
- Source: software flaw (wrong interpretation of break statement in C)
Ariane 5 Crash (1996)

- Crash of the European Ariane 5-missile in June 1996
- Costs: more than $500 million
- Source: software flaw in the control software
- A data conversion from a 64-bit floating point to 16-bit signed integer
- Efficiency considerations had led to the disabling of the software handler (in Ada)
Pentium FDIV Bug (1994)

- FDIV = floating point division unit
- Certain floating point division operations performed produced incorrect results
- Byte Mag: 1 in 9 billion floating point divisions with random parameters would produce inaccurate results
- Loss: $\approx 500$ million (all flawed processors were replaced) + enormous image loss of Intel Corp.
- Source: missing entries in a table
“It is fair to state, that in this digital era correct systems for information processing are more valuable than gold.”

Henk Barendregt
The Importance of Software Correctness

Rapidly increasing integration of ICT in different applications
- embedded systems
- communication protocols
- transportation systems
⇒ reliability increasingly depends on software!

Defects can be fatal and extremely costly
- products subject to mass-production
- safety-critical systems
What is System Verification?

Folklore “definition”
System verification amounts to check whether a system fulfills the qualitative requirements that have been identified.

Verification /= validation
- Verification = “check that we are building the thing right”
- Validation = “check that we are building the right thing”
Software Verification Techniques

Peer reviewing
- static technique: manual code inspection, no software execution detects
- between 31% and 93% of defects with median of about 60% subtle errors
- (concurrency and algorithm defects) hard to catch

Testing
- dynamic technique in which software is executed

Some figures
- 30% to 50% of software project costs devoted to testing
- more time and effort is spent on validation than on construction
- accepted defect density: about 1 defects per 1,000 code lines
Bug Hunting: the Sooner, the Better

![Graph showing the cost of introducing and detecting errors at different stages of software development.](image)
Formal Methods

Intuitive description

Formal methods are the
“applied mathematics for modeling and analyzing ICT systems”

Formal methods offer a large potential for:

- obtaining an early integration of verification in the design process
- providing more effective verification techniques (higher coverage)
- reducing the verification time

Usage of formal methods

Highly recommended by IEC, FAA, and NASA for safety-critical software
Formal Verification Techniques for Property $P$

**Deductive methods**
- method: provide a formal proof that $P$ holds
- tool: theorem prover/proof assistant or proof checker
- applicable if: system has form of a mathematical theory

**Model checking**
- method: systematic check on $P$ in all states
- tool: model checker (Spin, NuSMV, UppAal, ...)
- applicable if: system generates (finite) behavioral model

**Model-based simulation or testing**
- method: test for $P$ by exploring possible behaviors
Simulation and Testing

Basic procedure:
- take a model (simulation) or a realization (testing)
- stimulate it with certain inputs, i.e., the tests
- observe reaction and check whether this is “desired”

Important drawbacks:
- number of possible behaviors is very large (or even infinite)
- unexplored behaviors may contain the fatal bug

About testing . . .
- testing/simulation can show the presence of errors, not their absence
Milestones in Formal Verification

- **Mathematical program correctness**
  (Turing, 1949)

- **Proof-based technique for sequential programs**
  (Hoare, 1969)
  - for a given input, does a computer program generate the correct output?
  - based on compositional proof rules expressed in predicate logic

- **Proof-based technique for concurrent programs**
  (Pnueli, 1977)
  - handles properties referring to states during the computation
  - based on proof rules expressed in temporal logic

- **Automated verification of concurrent programs**
  - model-based instead of proof-rule based approach
  - does the concurrent program satisfy a given (logical) property?
Example Proof Rules

**Backward axiom**

\[
\{A[e/x]\} x := e \{A\}
\]

**Invariant rule**

\[
\{I \land b\} P \{I\}
\]

\[
\{I\} \text{ while } b \text{ do } P \{I \land \neg b\}
\]

**Cut rule**

\[
\{A\} P \{B\} \{B\} Q \{C\}
\]

\[
\{A\} P ; Q \{C\}
\]

**Logical rule**

\[
A \Rightarrow A' \{A'\} P \{B'\} \quad B' \Rightarrow B
\]

\[
\{A\} P \{B\}
\]

What is Model Checking?

**Informal description**

Model checking is an automated technique that, given a finite-state model of a system and a formal property, systematically checks whether this property holds for (a given state in) that model.
What are Models?
What are Models?

Transition systems
- States labeled with basic propositions
- Transition relation between states
- Action-labeled transitions to facilitate composition

Expressivity
- Programs are transition systems
- Multi-threading programs are transition systems
- Communicating processes are transition systems
- Hardware circuits are transition systems
- What else?
What are Properties?

Example properties
- Can the system reach a deadlock situation?
- Can two processes ever be simultaneously in a critical section?
- On termination, does a program provide the correct output?

Temporal logic
- Propositional logic
- Modal operators such as $\Box$ “always” and $\Diamond$ “eventually”
- Interpreted over state sequences (linear)
- Or over infinite trees of states (branching)
Model checking has been applied to several modules of this spacecraft launched in October 1998.
A Small Program Fragment

process Inc = while true do if $x < 200$ then $x := x + 1$ od

process Dec = while true do if $x > 0$ then $x := x - 1$ od

process Reset = while true do if $x = 200$ then $x := 0$ od

is $x$ always between (and including) 0 and 200 if it starts in this range?
int x = 0;

proctype Inc() {
    do :: true -> if :: (x < 200) -> x = x + 1 fi od
}

proctype Dec() {
    do :: true -> if :: (x > 0) -> x = x - 1 fi od
}

proctype Reset() {
    do :: true -> if :: (x == 200) -> x = 0 fi od
}

init {
    atomic{
        run Inc(); run Dec(); run Reset()
    }
}
How to Check?

Extend the model with a “monitor” process that checks $0 \leq x \leq 200$:

```plaintext
proc type Check() {
    assert (x >= 0 && x <= 200)
}

init {
    atomic{ run Inc(); run Dec(); run Reset(); run Check() }
}
```
A Counterexample

.......... 
605: proc 1 (Inc) line 9 "pan_in" (state 2) [((x<200))] 
606: proc 1 (Inc) line 9 "pan_in" (state 3) [x = (x+1)] 
607: proc 3 (Dec) line 5 "pan_in" (state 2) [((x > 0))] 
608: proc 1 (Inc) line 9 "pan_in" (state 1) [(1)] 
609: proc 3 (Reset) line 13 "pan_in" (state 2) [((x==200))] 
610: proc 3 (Reset) line 13 "pan_in" (state 3) [x = 0] 
611: proc 3 (Reset) line 13 "pan_in" (state 1) [(1)] 
612: proc 2 (Dec) line 5 "pan_in" (state 3) [x = (x-1)] 
613: proc 2 (Dec) line 5 "pan_in" (state 1) [(1)] 

spin: line 17 "pan_in", Error: assertion violated 
spin: text of failed assertion: assert(((x>=0)&&(x<=200))
Breaking the Error

```c
int x = 0;

proctype Inc() {
    do :: true -> atomic{ if :: x < 200 -> x = x + 1 fi } od
}

proctype Dec() {
    do :: true -> atomic{ if :: x > 0 -> x = x - 1 fi } od
}

proctype Reset() {
    do :: true -> atomic{ if :: x == 200 -> x = 0 fi } od
}

init {
    atomic{ run Inc() ; run Dec() ; run Reset() }
}
```
The Model Checking Process

- **Modeling phase**
  - model the system under consideration
  - as a first sanity check, perform some simulations
  - formalize the property to be checked

- **Running phase**
  - run the model checker to check the validity of the property in the model

- **Analysis phase**
  - property satisfied? → check next property (if any)
  - property violated? →
    - 1. analyze generated counterexample by simulation
    - 2. refine the model, design, or property ... and repeat the entire procedure
  - out of memory? → try to reduce the model and try again
The Pros of Model Checking

- widely applicable (hardware, software, protocol systems, ...)
- allows for partial verification (only most relevant properties)
- potential “push-button” technology (software-tools)
- rapidly increasing industrial interest
- in case of property violation, a counterexample is provided
- sound and interesting mathematical foundations
- not biased to the most possible scenarios (such as testing)
The Cons of Model Checking

- main focus on control-intensive applications (less data-oriented)
- model checking is only as “good” as the system model
- no guarantee about completeness of results
- impossible to check generalizations (in general)

Nevertheless:

Model checking is an effective technique to expose potential design errors
Striking Model-Checking Examples

- **Security**: Needham-Schroeder encryption protocol
  - error that remained undiscovered for 17 years unrevealed

- **Transportation systems**
  - train model containing $10^{476}$ states

- **Model checkers for C, Java and C++**
  - used (and developed) by Microsoft, Digital, NASA
  - successful application area: device drivers

- **Dutch storm surge barrier in Nieuwe Waterweg**

- **Software in the current/next generation of space missiles**
  - NASA’s Mars Pathfinder, Deep Space-1, JPL LARS group
Course Topics

What are appropriate models?
- transition systems
- from programs to transition systems
- from circuits to transition systems
- multi-threading, communication, ... 
- nanoPromela: an example modeling language

What are properties?
- safety: “something bad never happen”
- liveness: “something good eventually happen”
- fairness: “if something may happen frequently, it will happen”
Course Topics

How to check regular properties?
- finite-state automata and regular safety properties
- Büchi automata and ω-regular properties
- model checking: nested depth-first search

How to express properties succinctly?
- Linear-time Temporal Logic (LTL): syntax and semantics
- What can be expressed in LTL?
- LTL model checking: algorithms, complexity
- How to treat fairness in LTL
Course Topics

How to express properties **succinctly**?
- Computation Tree Logic (CTL): syntax and semantics
- What can be expressed in CTL?
- CTL model checking: algorithms, complexity
- How to treat fairness in CTL

How to make models smaller?
- Equivalences and pre-orders on transition systems
- Which properties are preserved?
- Minimization algorithms
Principles of Model Checking

Christel Baier
TU Dresden, Germany

Joost-Pieter Katoen
RWTH Aachen University, Germany

Gerard J. Holzmann, NASA JPL, Pasadena:
“This book offers one of the most comprehensive introductions to logic model checking techniques available today. The authors have found a way to explain both basic concepts and foundational theory thoroughly and in crystal clear prose.”
